    return a + b;  
}
```

```
add64:  
    adds r0, r0, r2  
    adcs r1, r1, r3  
    bx    lr
```

# **Negative (signed) Numbers**

Up to now, all binary numbers have been positive (unsigned)

How would you define negative (signed) numbers?

A clever way of defining -1 is to say that -1 is the number that when added to 1, results in 0 (mod 16)

$$0xf + 0x1 = 0x10 \% 16 = 0x0$$

0xf can be *interpreted* as -1

Note that modulo addition of signed numbers is exactly the same as addition of unsigned numbers!!

For 4-bit numbers,

0x0 = 0

0xf = -1

0xe = -2

...

0x8 = -8 (could be interpreted as 8)

0x7 = 7

...

0x1 = 1

0x0 = 0

if we choose to *interpret* 0x8 as -8,  
then the most-significant bit of the  
number indicates that it is negative (n)

## What is the maximum value for a int32?

606

integer

107 Why would you need the exact number? I remember " $(2^{31})-1$ " or " $\pm 2$  billion" and that's good enough for everything I ever needed. — Joachim Sauer Mar 3 '09 at 11:21

27 unsigned:  $2^{32}-1 = 4 \cdot 1024^3 - 1$ ; signed:  $-2^{31} \dots +2^{31}-1$ , because the sign-bit is the highest bit. Just learn  $2^0=1$  to  $2^{10}=1024$  and combine.  $1024=1k$ ,  $1024^2=1M$ ,  $1024^3=1G$  — comonad Mar 28 '11 at 20:01

6 I generally remember that every 3 bits is about a decimal digit. This gets me to the right order of magnitude: 32 bits is 10 digits. — Barnar Oct 2 '13 at 15:11

How do we negate an 8-bit number?

Subtract the number from 100000000!

```
11111111
10000000
 00000001
-----
11111111
```

11111111 (0xff) is -1

The 1's on the top are borrows

## Another way

Rewrite 100000000 as 11111111 + 1

$$-x = (11111111+1)-x = (11111111-x)+1 = \sim x+1$$

11111111

-00000001

-----

11111110 =  $\sim$ 00000001 (~ means flip bits)

11111110

+00000001

-----

11111111

**Subtraction is converted to**

$$a - b = a + \sim b + 1$$

$$01 - 00 = 01 + ff + 01 = 01 + c$$

$$01 - 01 = 01 + fe + 01 = 00 + c$$

$$01 - 02 = 01 + fd + 01 = ff$$

**Why?**

- Only one arithmetic op: add
- Need to think like this  
to understand when a carry is generated

sub32/

**00000000-00000000 = 00000000+ffffffff+1 = 00000000 Z=1, C=1**

**00000000-00000001 = 00000000+fffffffe+1 = ffffffff Z=0, C=0**

**ffffffff-00000001 = ffffffff+fffffffe+1 = ffffffffe Z=0, C=1**

**ffffffffe-00000001 = ffffffffe+fffffffe+1 = ffffffffd Z=0, C=1**

**...**

**00000000-ffffffff = 00000000+00000000+1 = 00000001 Z=0, C=0**

**00000001-ffffffff = 00000001+00000000+1 = 00000002 Z=0, C=0**

**00000001-fffffffd = 00000001+00000002+1 = 00000004 Z=0, C=0**

**...**

**ffffffff-ffffffff = ffffffff+00000000+1 = 00000000 Z=1, C=1**

**ffffffff-fffffffd = ffffffff+00000002+1 = 00000002 Z=0, C=1**

// What happens if the timer overflows?

```
unsigned timer_get_time(void) {  
    return GET32(SYSTIMERCLO);  
}
```

```
void delay_us(unsigned us) {  
    unsigned rb = timer_get_time();  
    while (1) {  
        unsigned ra = timer_get_time();  
        // subtraction results in a positive  
        // value even if the timer overflows  
        if( (ra-rb) >= us {  
            break;  
        }  
    }  
}
```

**Addition / subtraction of  
signed and unsigned numbers  
is the same!**

**Defined, Dangerous**

The semantics of numeric casts are:

Casting from a larger integer to a smaller integer (e.g. u32 -> u8) will truncate

Casting from a smaller integer to a larger integer (e.g. u8 -> u32) will zero-extend if the source is unsigned sign-extend if the source is signed

Casting between two integers of the same size (e.g. i32 -> u32) is a no-op

```

**Whenever you mix  
signed and unsigned numbers  
you get in trouble**

**Bjarne Stroustrup**

# **C Promotion Rules**

### 6.3.1.3 Signed and unsigned integers conversions

1 When a value with integer type is converted to another integer type, if the value can be represented by the new type, it is unchanged.

2 Otherwise, if the new type is unsigned, the value is converted by repeatedly adding or subtracting one more than the maximum value that can be represented in the new type until the value is in the range of the new type.

3 Otherwise, if the new type is signed and the value cannot be represented in it; either the result is implementation-defined or an implementation-defined signal is raised.

### 6.3.1.8 Usual arithmetic conversions

1 If both operands have the same type, then no further conversion is needed.

2 Otherwise, if both operands have signed integer types or both have unsigned integer types, the operand with the type of lesser integer conversion rank is converted to the type of the operand with greater rank.

3 Otherwise, if the operand that has unsigned integer type has rank greater or equal to the rank of the type of the other operand, then the operand with signed integer type is converted to the type of the operand with unsigned integer type.

4 Otherwise, if the type of the operand with signed integer type can represent all of the values of the type of the operand with unsigned integer type, then the operand with unsigned integer type is converted to the type of the operand with signed integer type.

5 Otherwise, both operands are converted to the unsigned integer type corresponding to the type of the operand with signed integer type.
